What is a filter?

A filter is a set of judgment conditions that the program uses to match against every captured packet. If match result is positive, the packet is accepted and analyzed. If negative, the program will ignore it. In Capsa, you can manage your filters conveniently and easily create a new one.

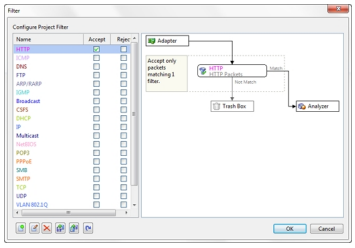

To manager filters:

- On Start Page: Click Packet Filter Settings link (the right panel).
- In a capture: Click Filter icon in the Analysis tab of the Ribbon.

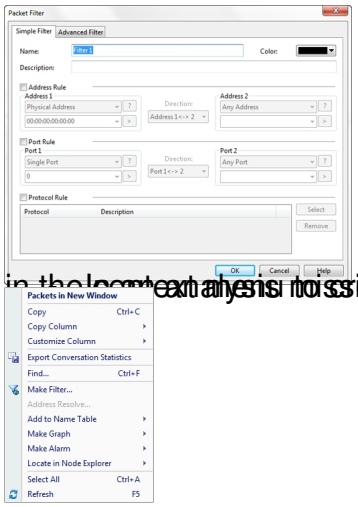

To enable a filter:

This window lists all your filters, to enable one, just check the accept checkbox (no filter enabled by default). And you will see how the filters will work to process the packets in the right panel.

To create a filter:

- In the Filter window, click Add button to open the Packet Filter window to create a new filter. To build a simple one, you can use three condition rules: Address (IP and MAC address), Port number, protocol.

in the [illegible] analysis mode, you can also right-click a statistic item and select Make Filter
